## 1 Preface

gStore<sup>1</sup> is a graph-based database management system, which keeps the structure of original RDF<sup>2</sup> data.

The data model is directed graph with labels, and each vertex corresponds to a subject or object.

Given a SPARQL<sup>3</sup> query(only select...where clause is well supported now), gStore will transfer it to a directed graph with labels first.

Then the query problem will be equivalent to a subgraph matching problem. An index called VSTree is used in gStore to speed up the matching process. For each variable in the SPARQL query, gStore acquires its candidates through VSTree, and finally a join process is performed to get the final result.

We compare the performance of gStore with apache-jena<sup>4</sup>, openrdf-sesame<sup>5</sup> and virtuoso-openlinksw<sup>6</sup> on several RDF datasets. The items needing to be considered include the time to build database, the size of database and the time to answer each SPARQL query. In addition, we will give a special explanation if the query results of each database do not match. (we will not consider the memory and disk cost except for special cases)

## 2 Environment Setup

The experiment is finished on a Linux server, whose configuration is as follows:

Server	CentOS7
IP	172.31.222.78
memory	128G
disk	4T

Table 1: environment

The versions of all database management systems used here are all open source. Latest versions are choosed:

DBMS	VERSION
gStore	0.5.0
apache-jena	3.0.1
virtuoso-openlinksw	7.2

Table 2: dbms series

We should not include the time to load database indexes(called offline time) when comparing the time to answer SPARQL queries. And we need to empty the buffer and cache of operation system when the experiment for each database management system is over.

Besides, the time to answer a query shouldn't be too long. We will kill the running program if the time consumed is larger than 30 minutes, and set the running time as 1800000ms.

The datasets used include WatDiv<sup>7</sup>, LUBM<sup>8</sup>, BSBM<sup>9</sup> and DBpedia<sup>10</sup>. DBpedia are the background data of wikipedia, while the others are generated by programs. SPARQL queries are generated by programs or copied from other essays. In addition, we now plus the Freebase dataset now, which has 2 billions of triples.

All datasets and queries we used are listed in this document, to provide a more thorough understanding of the experiment.

Below is for the WatDiv datasets, and the corresponding queries are placed in WatDiv Queries.

Dataset	Size(B)	Triple	Predicate	Entity	Literal
watdiv10M	15,743,004,966	109,795,918	86	5,212,745	5,077,247
watdiv100M	15,743,004,966	109,795,918	86	5,212,745	5,077,247
watdiv200M	31,712,545,025	219,714,495	86	10,424,745	9,976,964
watdiv300M	47,676,280,476	329,584,783	86	15,636,745	14,748,846
watdiv500M	72,326,509,429	500,000,000	76	26,060,745	23,964,574

Table 3: WatDiv series

Below is for the LUBM datasets, and the corresponding queries are placed in LUBM Queries.

Below is for the DBpedia datasets, and the corresponding queries are placed in DBpedia Queries.

Below is for the Freebase datasets, and the corresponding queries are placed in Freebase Queries. Notice that we only use freebase2B(which is a subset of freebase2.5B, only includes the English part) in this test, because Jena and Virtuoso can not run the whole freebase datset due to format limitations.

## 4 Modification

We provide insertion and deletion in gStore v0.5.0. You can either insert/delete from a given RDF file, or just run sparql queries to insert/delete something. If you want to modify something, you need to delete it and reinsert. The cost of insertion and deletion are recorded in table 9, where the time unit is ms. We first build the database from lubm500M dataset, and then remove the first 30000 triples of the dataset from teh database. Finally, we add the removed triples again to acquire a complete database. (The answers of queries are all right.)

Dataset	build	insert	delete
lubm500M	5,348,766	3,500,000	3,700,000

Table 9: Insertion and Deletion

## 5 Conclusion

This section is not tested and updated in gStore v0.5.0.

gStore can go well with RDF datasets which are in N-Triples format and TTL format, while the other database management systems may come across some questions. In addition, gStore outperforms other systems on many SPARQL queries. What is more, gStore is highly extensively because it uses graph model instead of relational model.

However, there are also some shortcomings for gStore:

- 1. RDF datasets in XML format are not supported
- 2. the disk cost is high
- 3. gStore is sometimes slower

Besides, gStore v0.5.0 does not generate solutions for satellites which are not selected. This will speed up the query answering process, while not keeping so many duplicates in the result set. For example, in below query, let's assume that ?s has only one unique answer, but ?o1 and ?o2 both have 10,000 answers. In previous versions of gStore, there are 100,000,000 records in the result set because we have to find the answer of ?s and generate the solutions for ?o1 and ?o2, even if only ?s is selected in the sparql query. However, in the v0.5.0, we find the answer of ?s and return directly. In this case, there won't be so many duplicates in the result set as before, but this is ok.

Out of question, the performance of gStore can be improved a lot later. The future work is listed below:

- 1. fix the problem in insertion/deletion
- 2. support datasets of 1 billion triples in a single machine(only 500 million now)
- 3. add unit testing for the whole system(only black-box testing now)
- 4. do code level optimization(for example, large loop in Join module)
- 5. speed up the table join process using pipeline

## 6 Appendix

## 6.1 WatDiv queries

These queries come from [3].

## 6.2 LUBM queries

This queries come from two places.  $q1 \sim q7$  come from [1] and [3].  $q8 \sim q21$  come from [2] and [4].

#### 6.2.1 q1.sql

```
select ?x where
 ?x
         <rdf:type>
                          <ub:GraduateStudent>.
         <rdf:type>
                          <ub: University >.
 ?y
 ?z
         <rdf:type>
                          <ub:Department>.
 ?x
         <ub:memberOf> ?z.
 ?z
         <ub:subOrganizationOf> ?y.
         <ub:undergraduateDegreeFrom>
 ?x
```

#### 6.2.2 q2.sql

### 6.2.3 q3.sql

```
select ?x where
{
         <rdf:type>
                          <ub:UndergraduateStudent>.
 ?x
          <rdf:type>
                          <ub: University >.
 ?y
         <rdf:type>
                          <ub:Department>.
 ?z
 ?x
          <ub:memberOf> ?z.
 ?z
          <ub:subOrganizationOf> ?y.
 ?x
          <br/><b:undergraduateDegreeFrom>
